

# TensorFlow & Keras

## An Introduction

(Some of the contents on these slides, along with the template, have been adopted from William Guss (ex TA) and CS 224 and CS20 at Stanford)

# Deep Learning Frameworks

- Scale ML code
- Compute Gradients!
- Standardize ML applications for sharing
- Interface with GPUs for parallel processing

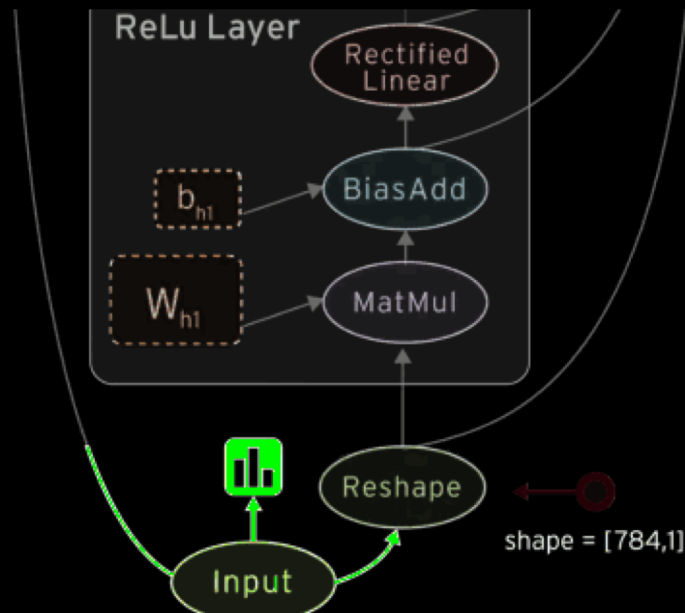

TensorFlow

# What is TensorFlow?

TensorFlow is a graph computation framework for deep learning.

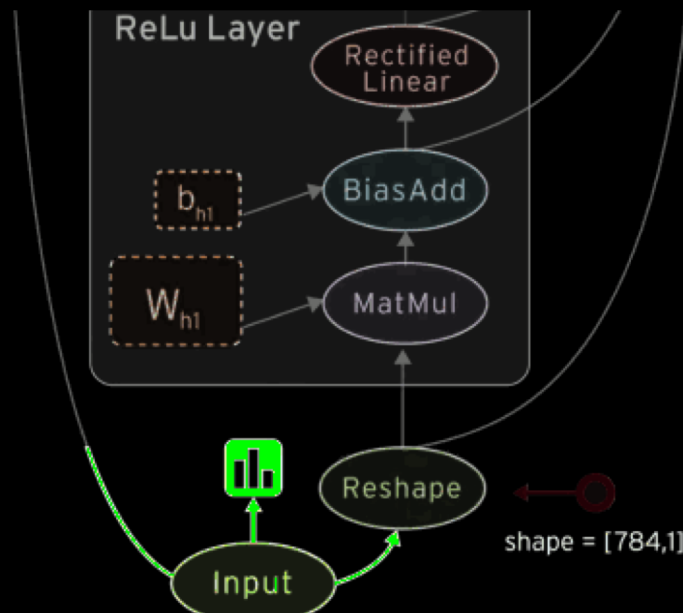

Originally developed by Google Brain Team to conduct ML research

# What is TensorFlow?

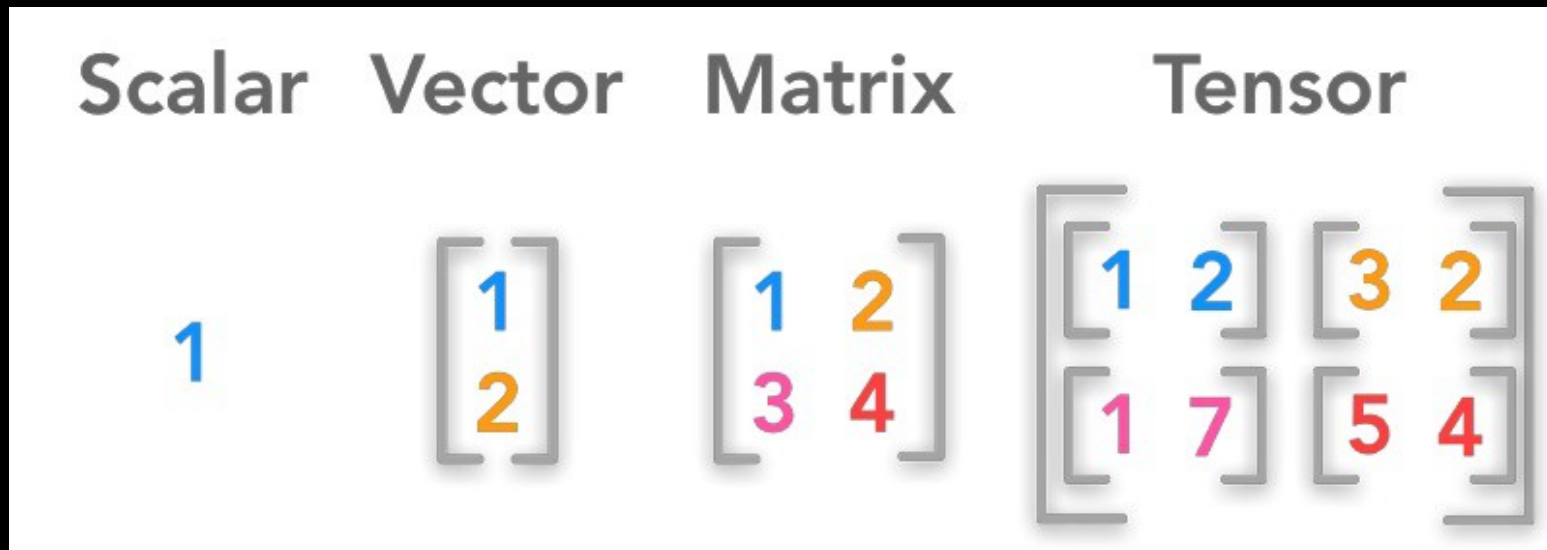

TensorFlow allows for the specification and optimization of complex feed-forward models.

In particular, TensorFlow automatically differentiates a specified model.

# What is a tensor?

- An n-dimensional Array

# Why TensorFlow?

- Python API
- Portability: deploy computation to one or more CPUs or GPUs in a desktop, server, or mobile device with a single API
- Visualization: TensorBoard
- Auto-differentiation
- Large community (> 10,000 commits and > 3000 TF-related repos in 1 year)
- Awesome projects already using TensorFlow

# A motivating example

## The NumPy approach

```
net1 = W1 @ x + b1
h = s(net1)
net2 = W2 @ h + b2
output = s(net2)

# Manually compute derivative for W2

$$\frac{dL}{d_{\text{output}}} = (\text{output} - \text{label})$$

$$\frac{dL}{dW_2} = \frac{dL}{d_{\text{output}}} @ \frac{ds}{d_{\text{net}}}(\text{net}) @ h$$

W2 -= learning_rate *  $\frac{dL}{dW_2}$ 
# Repeat for all other variables :
```

## The TensorFlow approach

```
net1 = W1 @ x + b1
h = tf.nn.sigmoid(net1)
net2 = W2 @ h + b2
output = tf.nn.sigmoid(net2)

# Let tensorflow do the heavy lifting
optimizer = tf.train.AdamOptimizer(learning_rate)
train = optimizer.minimize(L)

# Done :)
```

# Programming Model

Big idea: express a numeric computation as a **graph**

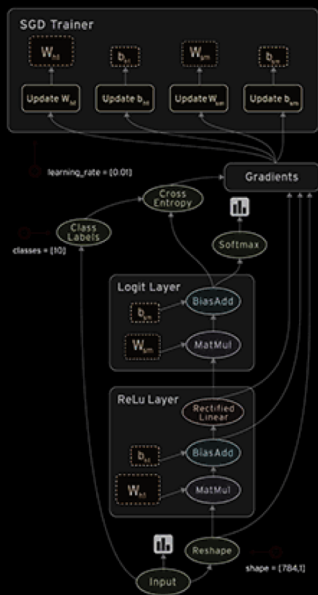

- Graph nodes are **operations** which have any number of inputs and outputs
- Graph edges are **tensors** which flow between nodes

# Programming Model

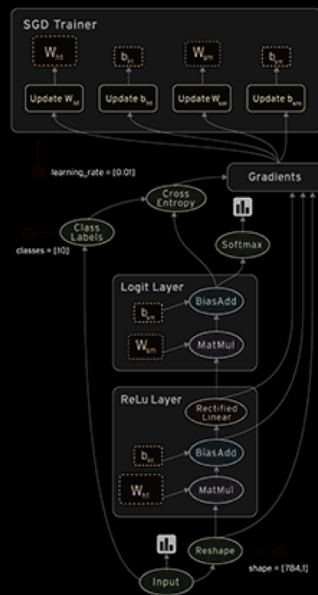

$$h = \text{ReLU}(Wx + b)$$

# TensorFlow Basics

Construction

Execution

# TensorFlow Basics: Construction

## Placeholders (`tf.Placeholder`)

- Allow data to be **fed** into the computation graph at **execution time** (e.g. features, labels)

```
x = tf.Placeholder  
      (float)
```

```
y = tf.constant(5.0)
```

## Variables (`tf.Variable`)

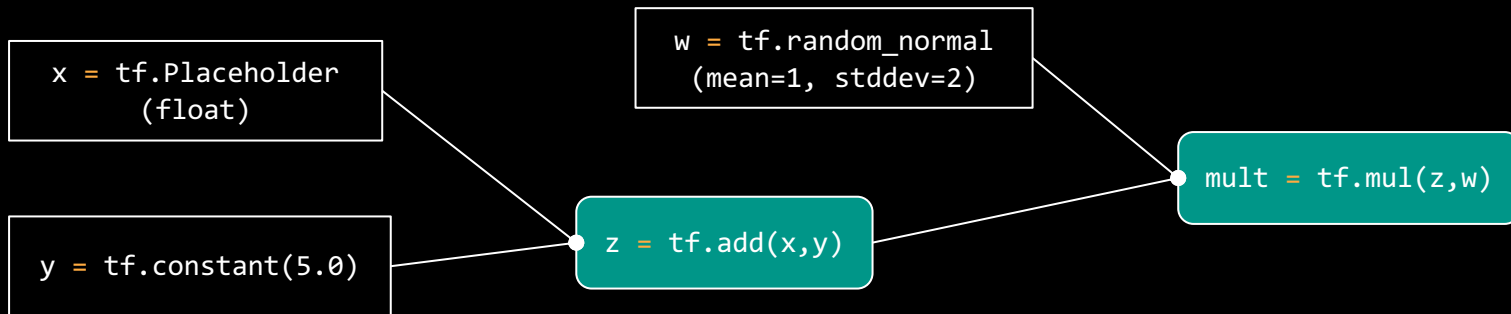

- Store **parameters** in graph
- Can be **trainable** (optimized during backprop) or **untrainable**
- Variety of **initializers** (e.g. constant, normal)

```
w = tf.random_normal  
      (mean=1, stddev=2)
```

# TensorFlow Basics: Construction

## Operations (`tf.Operation`)

- Takes in `variable` and/or outputs from other operations.
- Can be `fed` into other operations and linked in the graph.
- This includes linear algebraic operations and optimizers.

# In Code

1. Create weights, including initialization

$$W \sim \text{Uniform}(-1, 1); b = 0$$

1. Create input placeholder x

m \* 784 input matrix

1. Build flow graph

```
import tensorflow as tf

b = tf.Variable(tf.zeros((100,)))
W = tf.Variable(tf.random_uniform((784, 100), -1, 1))

x = tf.placeholder(tf.float32, (100, 784))

h = tf.nn.relu(tf.matmul(x, W) + b)
```

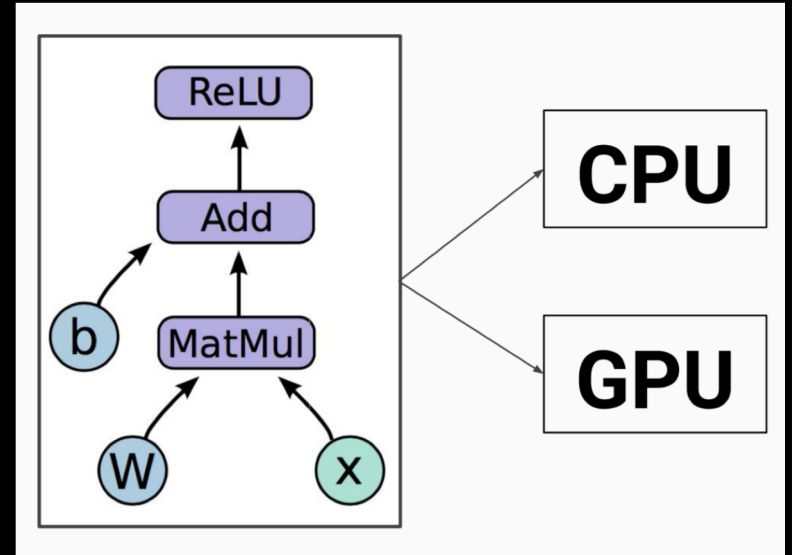

$$h = \text{ReLU}(Wx + b)$$

# How do we run it?

So far we only talked about defining a **graph**

We can deploy this graph with a **session** - a binding to a particular execution context (e.g. CPU, GPU)

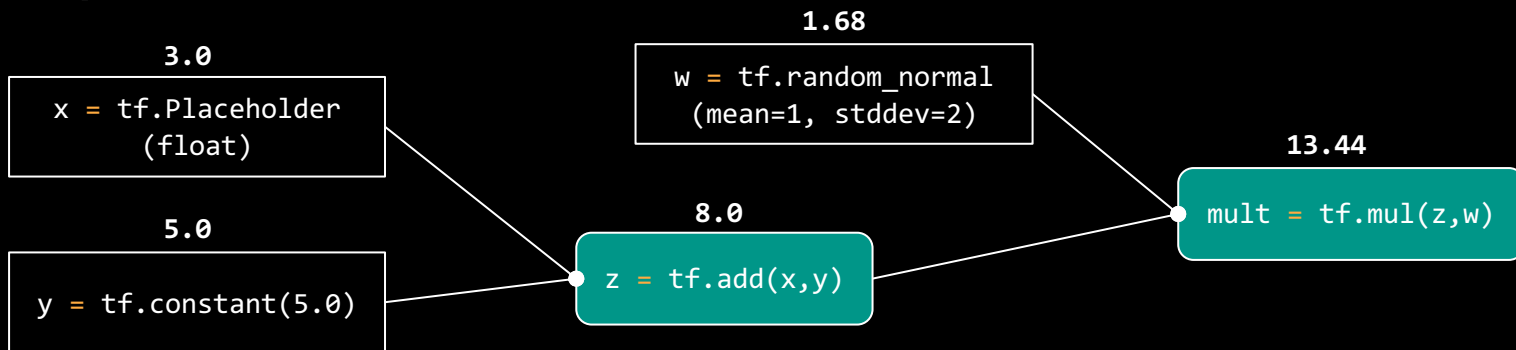

# TensorFlow Basics: Execution

## Sessions (`tf.Session`)

- Handles post-construction interactions with the graph
- Call the `run` method to evaluate tensors

```
sess = tf.Session()
sess.run(tf.global_variables_initializer())
sess.run(mult, feed_dict={
    x: 3.0}) # 13.44
```

# Getting Output

```
sess.run(fetches, feeds)
```

**Fetches:** List of graph nodes. Return the outputs of these nodes.

**Feeds:** Dictionary mapping from graph nodes to concrete values. Specifies the value of each graph node given in the dictionary.

```
import numpy as np
import tensorflow as tf

b = tf.Variable(tf.zeros((100,)))
W = tf.Variable(tf.random_uniform((784, 100),
                                  -1, 1))

x = tf.placeholder(tf.float32, (100, 784))
h = tf.nn.relu(tf.matmul(x, W) + b)

sess = tf.Session()
sess.run(tf.initialize_all_variables())
sess.run(h, {x: np.random.random(100, 784)})
```

# So far

We first built a **graph** using **variables** and **placeholders**

We then deployed the graph onto a **session**, which is the **execution environment**

Next we will see how to **train a model**

# Define Loss?

Use `placeholder` for labels

Build loss node using labels and `prediction`

```
prediction = tf.nn.softmax(...) #Output of neural network
label = tf.placeholder(tf.float32, [100, 10])

cross_entropy = -tf.reduce_sum(label * tf.log(prediction), axis=1)
```

# Compute Gradients?

```
train_step = tf.train.GradientDescentOptimizer(0.5).minimize(cross_entropy)
```

- **tf.train.GradientDescentOptimizer** is an Optimizer object
- **tf.train.GradientDescentOptimizer(lr).minimize(cross\_entropy)** adds optimization operation to computation graph

# Compute Gradients?

```
train_step = tf.train.GradientDescentOptimizer(0.5).minimize(cross_entropy)
```

TensorFlow graph **nodes** have **attached gradient operations**

Gradient with respect to parameters computed with backpropagation

... **automatically**

# TensorFlow for Deep Learning

TensorFlow has first class support for **high** and **low-level** deep learning `tf.Operations`.

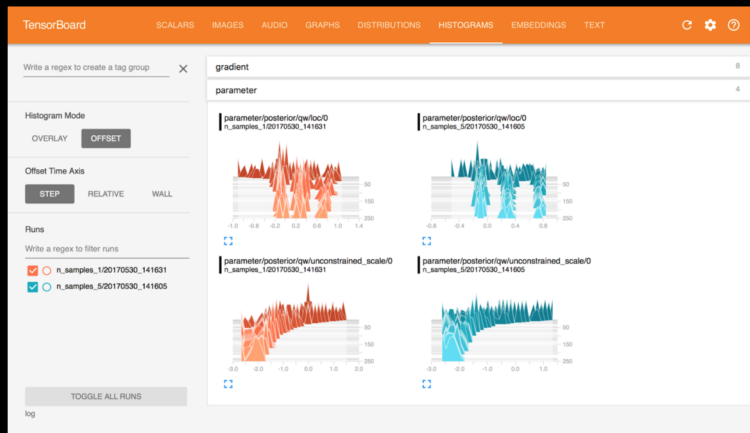

# In Summary

1. Build a graph
  - a. Feedforward / Prediction
  - b. Optimization (gradients and train\_step operation)
2. Initialize a session
3. Train with `session.run(train_step, feed_dict)`

Demo

# Visualizing Learning: TensorBoard

TensorBoard provides a visual representation of the **graph** and the **performance** of optimizers.

Keras

# Keras is the official high-level API of TensorFlow

- tensorflow.keras (tf.keras) module
- Part of core TensorFlow since v1.4
- Full Keras API
- Better optimized for TF
- Better integration with TF-specific features

# What's special about Keras?

- A focus on user experience.
- Large adoption in the industry and research community.
- Multi-backend, multi-platform.
- Easy productization of models.

# User Experience

**Keras is an API designed for human beings, not machines.** Keras follows best practices for reducing cognitive load: it offers consistent & simple APIs, it minimizes the number of user actions required for common use cases, and it provides clear and actionable feedback upon user error.

**This makes Keras easy to learn and easy to use.** As a Keras user, you are more productive, allowing you to try more ideas than your competition, faster -- which in turn helps you win machine learning competitions.

**This ease of use does not come at the cost of reduced flexibility:** because Keras integrates with lower-level deep learning languages (in particular TensorFlow), it enables you to implement anything you could have built in the base language. In particular, as `tf.keras`, the Keras API integrates seamlessly with your TensorFlow workflows.

Using Keras

# Three API Styles

- The Sequential Model
  - Dead simple
  - For single-input, single-output, sequential layer stacks
  - Good for 70+% of use cases
- The functional API
  - Like playing with Lego bricks
  - Multi-input, multi-output, arbitrary static graph topologies
  - Good for 95% of use cases
- Model Subclassing
  - Maximum flexibility
  - Larger potential error surface

# The Sequential API

```
import keras
from keras import layers

model = keras.Sequential()
model.add(layers.Dense(20, activation='relu', input_shape=(10,)))
model.add(layers.Dense(20, activation='relu'))
model.add(layers.Dense(10, activation='softmax'))

model.fit(x, y, epochs=10, batch_size=32)
```

# The functional API

```
import keras
from keras import layers

inputs = keras.Input(shape=(10,))
x = layers.Dense(20, activation='relu')(x)
x = layers.Dense(20, activation='relu')(x)
outputs = layers.Dense(10, activation='softmax')(x)

model = keras.Model(inputs, outputs)
model.fit(x, y, epochs=10, batch_size=32)
```

# Model Subclassing

```
import keras
from keras import layers

class MyModel(keras.Model):

    def __init__(self):
        super(MyModel, self).__init__()
        self.dense1 = layers.Dense(20, activation='relu')
        self.dense2 = layers.Dense(20, activation='relu')
        self.dense3 = layers.Dense(10, activation='softmax')

    def call(self, inputs):
        x = self.dense1(x)
        x = self.dense2(x)
        return self.dense3(x)

model = MyModel()
model.fit(x, y, epochs=10, batch_size=32)
```
